

ANGULAR FRAMEWORK

What is Angular

- Angular is a development platform, built on **TypeScript**. As a platform, Angular includes:
 - A component-based framework for building scalable web applications
 - A collection of well-integrated libraries that cover a wide variety of features, including routing, forms management, client-server communication, and more
 - A suite of developer tools to help you develop, build, test, and update your code

FEATURES & BENEFITS

CROSS PLATFORM

Progressive Web Apps	Native	Desktop
Use modern web platform capabilities to deliver app-like experiences. High performance, offline, and zero-step installation.	Build native mobile apps with strategies from Cordova, Ionic, or NativeScript.	Create desktop-installed apps across Mac, Windows, and Linux using the same Angular methods you've learned for the web plus the ability to access native OS APIs.

FEATURES & BENEFITS

SPEED AND PERFORMANCE

Code Generation	Universal	Code Splitting
Angular turns your templates into code that's highly optimized for today's JavaScript virtual machines, giving you all the benefits of hand-written code with the productivity of a framework.	Serve the first view of your application on Node.js®, .NET, PHP, and other servers for near-instant rendering in just HTML and CSS. Also paves the way for sites that optimize for SEO.	Angular apps load quickly with the new Component Router, which delivers automatic code-splitting so users only load code required to render the view they request.

FEATURES & BENEFITS

PRODUCTIVITY

Templates	Angular CLI	IDEs
Quickly create UI views with simple and powerful template syntax.	Command line tools: start building fast, add components and tests, then instantly deploy.	Get intelligent code completion, instant errors, and other feedback in popular editors and IDEs.

Single Page Application (SPA)

- A single page application is a web application or a website which provides users a very fluid, reactive and fast experience similar to a desktop application.
- it dynamically rewrites the current page rather than loading entire new pages from a server. That's the reason behind its reactive fast speed.
- The goal is faster transitions that make the website feel more like a native app.

TypeScript

- TypeScript is a programming language developed and maintained by Microsoft.
- TypeScript is a **statically-typed superset** of JavaScript.
- Every JavaScript program is also a TypeScript program. In TypeScript, there's some extra syntax: you can add type declarations, type annotations, type assertions, type guards, and type aliases.

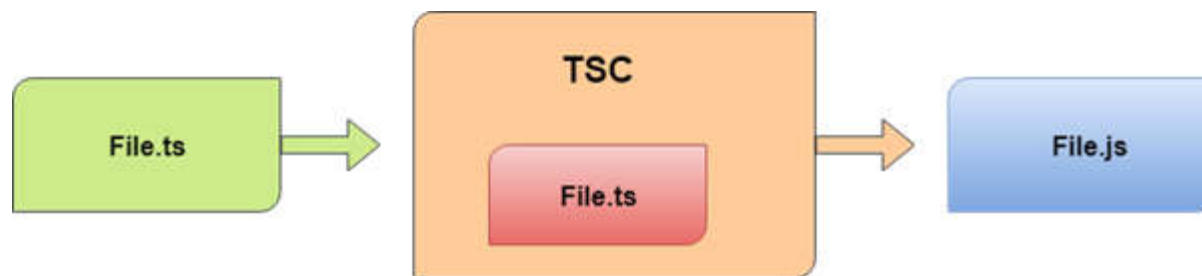

TypeScript

- TypeScript cannot run directly on the browser. It needs a compiler to compile the file and generate it in JavaScript file, which can run directly on the browser.
- The TypeScript source file is in ".ts" extension. We can use any valid ".js" file by renaming it to ".ts" file.
- TypeScript uses TSC (TypeScript Compiler) compiler, which convert Typescript code (.ts file) to JavaScript (.js file).

Advantages

- TypeScript supports Static typing, Strongly type, Modules, Optional Parameters, etc.
- TypeScript supports object-oriented programming features such as classes, interfaces, inheritance, generics, etc.
- TypeScript is fast, simple, and most importantly, easy to learn.
- TypeScript provides the error-checking feature at compilation time. It will compile the code, and if any error found, then it highlighted the mistakes before the script is run.

Advantages

- TypeScript supports all JavaScript libraries because it is the superset of JavaScript.
- TypeScript support reusability because of the inheritance.
- TypeScript make app development quick and easy as possible, and the tooling support of TypeScript gives us autocompletion, type checking, and source documentation.

Advantages

- TypeScript has a definition file with .d.ts extension to provide a definition for external JavaScript libraries.
- TypeScript supports the latest JavaScript features, including ECMAScript 2015.
- TypeScript gives all the benefits of ES6 plus more productivity.
- Developers can save a lot of time with TypeScript.

16

Angular CLI

- The Angular CLI is a **command-line interface** tool that you use to initialize, develop, scaffold, and maintain Angular applications directly from a command shell.
- Install the CLI using the npm package manager:

```
npm install -g @angular/cli
```

Angular CLI

- Check Version
`ng version`
- Angular app initialize
`ng init`
- Angular New App creation
`ng new <app-name>`
- Angular serve application
`ng serve`

Angular CLI

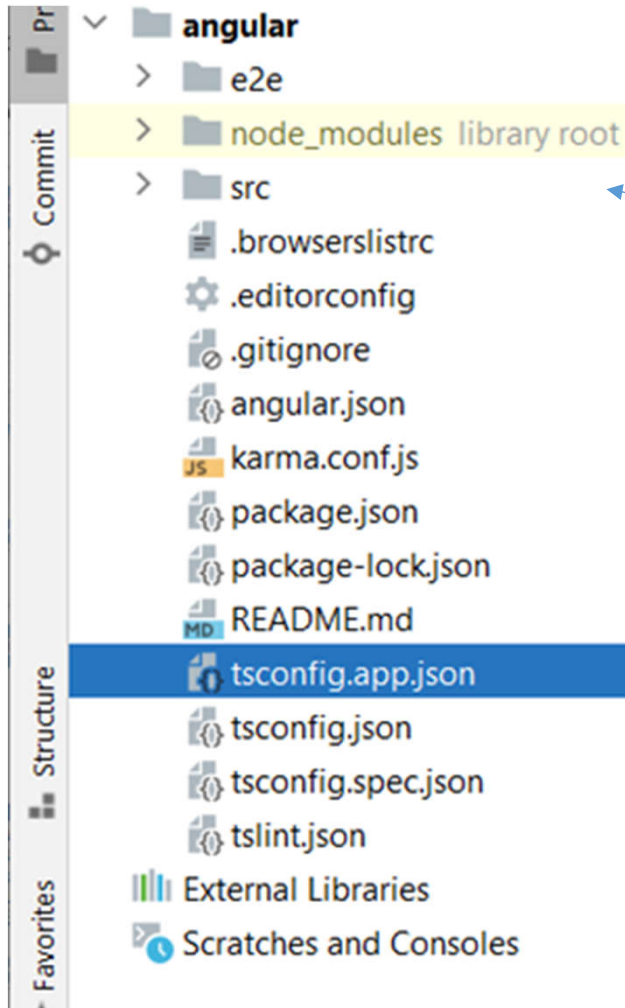

- Angular ng generate component
`ng generate component <component-name>`
`ng g c <component-name>`
- Generate class
`ng g c <class-name>`
- Generate module
`ng g c <module>`
- Generate service
`ng g p <service-name>`

20

Angular App structure

Root Lib

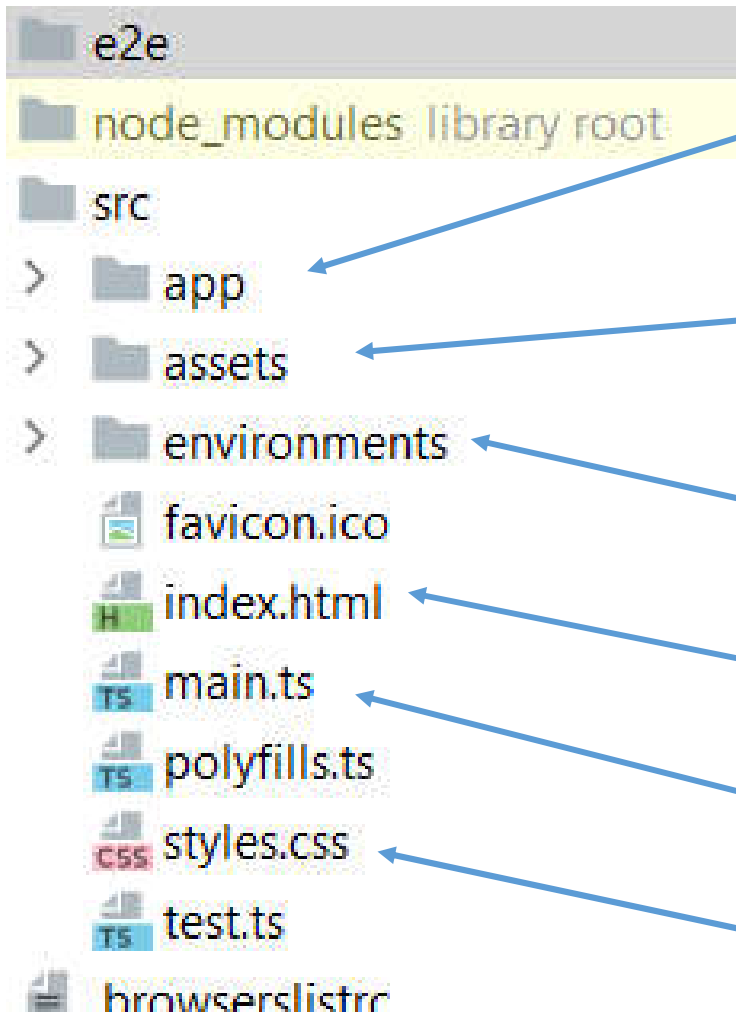

Source files for the root-level application project.

21

Angular App structure

Contains the component files in which your application logic and data are defined.

Contains image and other asset files to be copied as-is when you build your application.

Contains build configuration options for particular target environments

The main HTML page that is served when someone visits your site.

The main entry point for your application.

Lists CSS files that supply styles for a project.

22

Component

- Components are the main building block for Angular applications. Each component consists of:
 - An HTML template that declares what renders on the page
 - A Typescript class that defines behavior
 - A CSS selector that defines how the component is used in a template
 - Optionally, CSS styles applied to the template

Template

- In Angular, a template is a chunk of HTML. Within a template, you can use special syntax to leverage many of Angular's features.
- Each Angular template in your app is a section of HTML that you can include as a part of the page that the browser displays. An Angular HTML template renders a view, or user interface, in the browser, just like regular HTML, but with a lot more functionality.
